

ABSTRACT

It is an object to achieve both improvements in system capacity and load distribution, by allocating resources so as not to generate the call loss as possible.

- 5 A protected call is set, the resource allocating scheme is varied according to the resource state of each card, call allocating processing is performed to distribute loads at the low traffic time, while being performed to use up as possible resources of a card with a high in-use
- 10 rate at the high traffic time, and it is thereby possible to obtain the advantageous effect of using resources with high efficiency to enable the load distribution over signal processing cards without generating the call loss as possible.
